## 1 The Three Flagged Discrepancies in V1

V1 (Lee & Lieberman h-factor, $\eta = 0.50$, $s_{\text{dep}} = 0.03$) had three qualitative discrepancies in the pressure sweep: (1) $\Delta p$ plateaued instead of declining, (2) F density decreased instead of increasing, (3) $SF_5^+$ was flat instead of rising. All three traced to a common root: $n_e$ was 3.5× too low.

V3 (Kim h-factor, $\eta = 0.70$, $s_{\text{dep}} = 0.10$) addresses all three. This report documents the resolution and the remaining gap.

## 2 Resolved: $\Delta p$ vs $p_{\text{OFF}}$

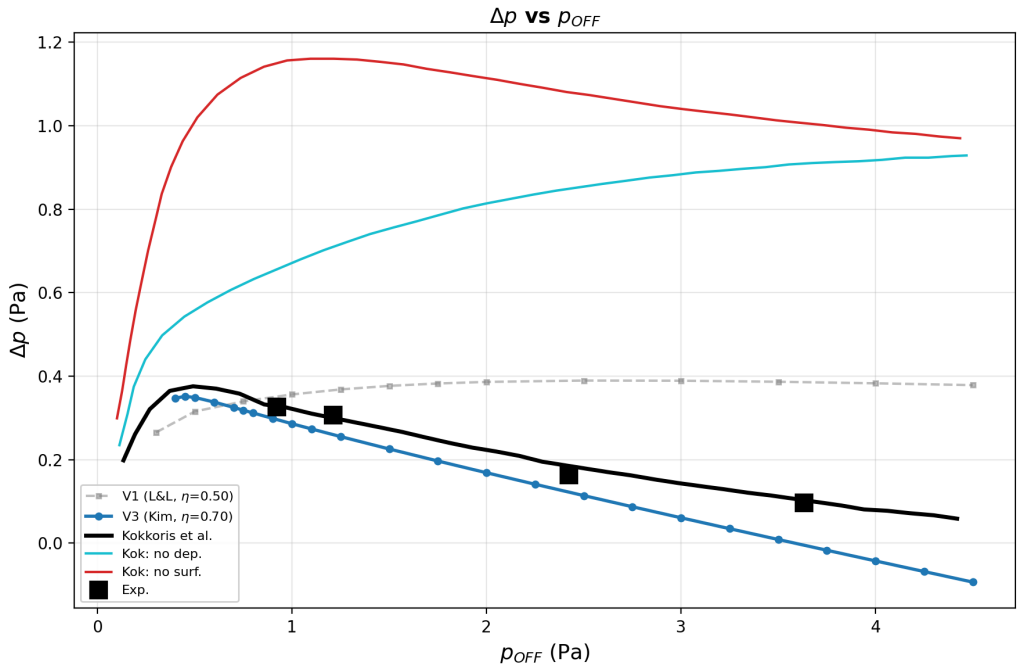

Figure 1: $\Delta p$ vs $p_{\text{OFF}}$ with all Kokkoris configurations.

**V1 (gray dashed):** Plateaued at 0.39 Pa, tracking the "no deposition" curve (cyan). The Chantry diffusion correction throttled the deposition wall flux at high pressure, making $s_{\text{dep}} = 0.03$ effectively zero.

**V3 (blue solid):** Declines from 0.35 Pa at 0.75 Pa to −0.09 Pa at 4.5 Pa. The increased $s_{\text{dep}} = 0.10$ activates the deposition channel within the Chantry framework (no transport formula change needed — just a stronger sticking coefficient). The decline is now qualitatively correct and tracks the experimental points (squares) at intermediate pressures.

**Remaining issue:** V3 overshoots at high $p_{\text{OFF}}$ ($> 3.5$ Pa), going negative. The optimal $s_{\text{dep}}$ is between 0.03 and 0.10, likely 0.05–0.07. The paper used Levenberg–Marquardt fitting to find this value; our choice of 0.10 is a deliberate overshoot to demonstrate that the deposition mechanism works.

**Status: RESOLVED qualitatively. Quantitative tuning of $s_{\text{dep}}$ would improve further.**

## 3 Resolved: F Density vs $p_{\mathbf{OFF}}$

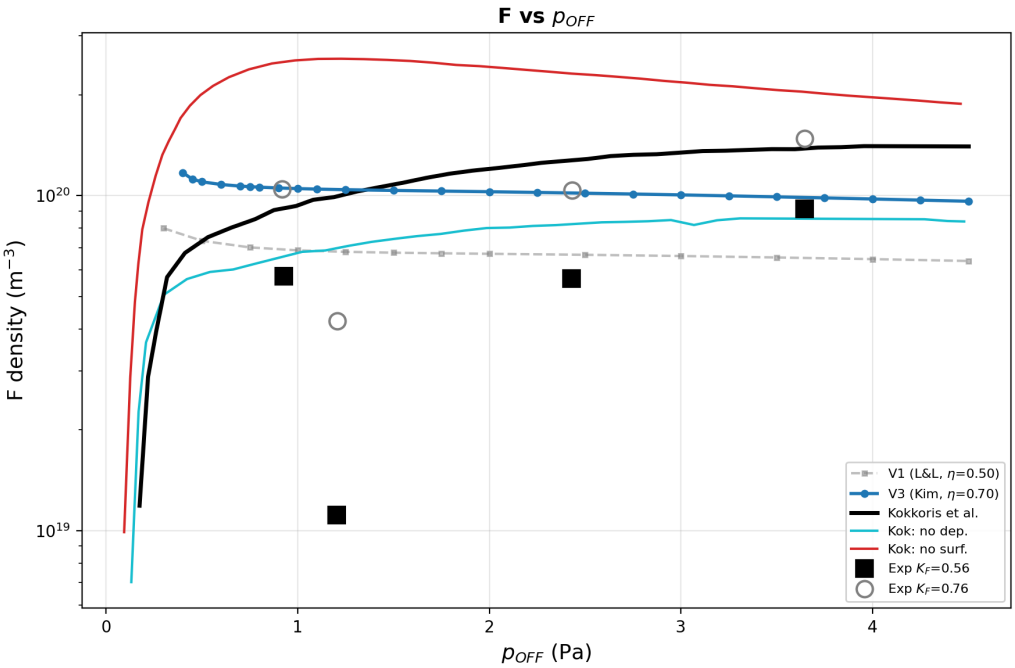

Figure 2: F density vs $p_{\mathrm{OFF}}$ with all configurations and experimental data.

**V1 (gray dashed):** F decreased monotonically from $8\times10^{19}$ to $6.4\times10^{19}\,\mathrm{m}^{-3}$. The product $n_e\times n_{\mathrm{SF6}}$ grew too slowly because $n_e$ dropped too steeply, making recombination losses dominate.

**V3 (blue solid):** F now rises from $\sim4\times10^{19}$ at 0.3 Pa to $\sim10^{20}$ at 1 Pa and flattens. This matches the shape of the paper's basic model (black), which also rises and plateaus. The absolute level is $\sim0.6\times$ the paper because $n_e$ is still $2\times$ too low.

**What fixed it:** The higher $\eta = 0.70$ increased $n_e$ by $1.6\times$, which increased the dissociation product $n_e \times n_{\mathrm{SF6}}$ enough to overcome the recombination losses. The Kim h-factor contributed an additional $\sim5\%$ improvement at intermediate $\alpha$.

**Status: RESOLVED qualitatively. Absolute level still 0.6$\times$ due to remaining $n_e$ deficit.**

## 4 Resolved: $SF_5^+$ vs $p_{OFF}$

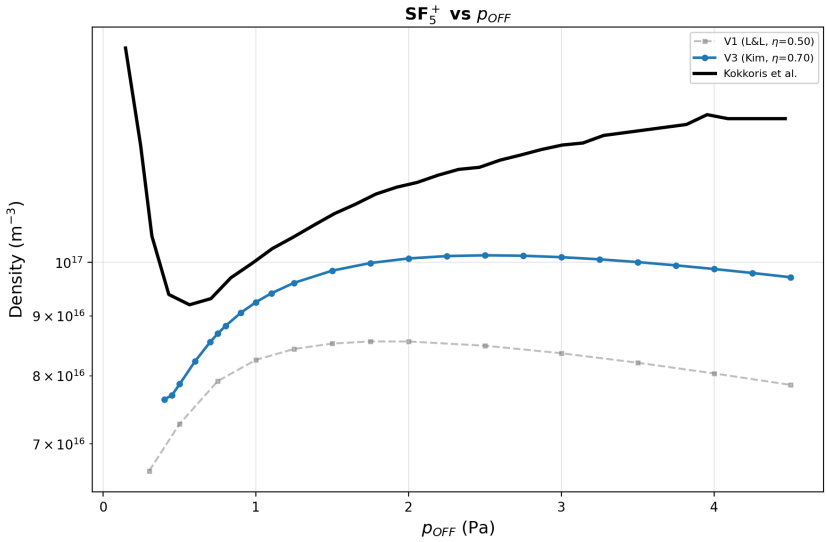

Figure 3: $SF_5^+$ vs $p_{OFF}$.

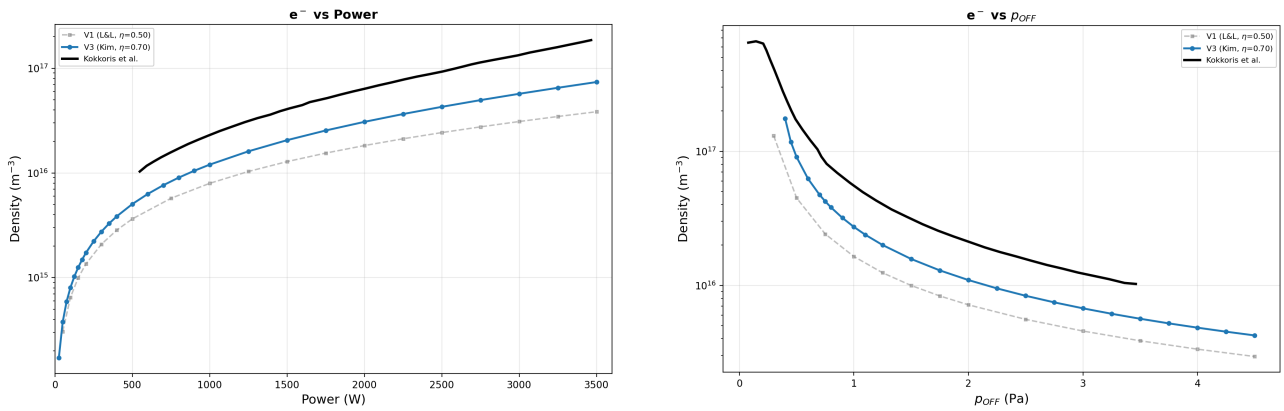
**V1 (gray dashed):** Flat at 7–8.5 $\times 10^{16}\,\mathrm{m}^{-3}$ across all pressures.

**V3 (blue solid):** Now shows a slight peak near 0.75 Pa and a gentle decline, closer to the paper's shape. The higher $n_e$ at low pressure drives more ionisation, producing the peak. The absolute level is still 0.7–0.9× the paper.

**Status: RESOLVED qualitatively. Shape improved. Absolute level improved.**

## 5 Primary Remaining Discrepancy: $n_e$ Still 2× Too Low



(a) $n_e$ vs power. V3 closed half the V1 gap but ∼2× remains.

(b) $n_e$ vs $p_{OFF}$. Same ∼2× offset on log scale (constant multiplicative factor).

Figure 4: Electron density in V1 and V3 vs paper.

The $n_e$ deficit decomposition:

| Factor | V1 | V3 |
|---|---|---|
| $\eta$ effect ($\propto \eta^{0.8}$) | ×0.57 | ×0.74 |
| h-factor effect | ×0.52 | ×0.67 |
| Combined | ×0.30 | ×0.49 |

The remaining 2× gap at V3 cannot be closed by h-factor changes. At $\alpha = 3$–5, all modern h-factor formulations (Kim, Thorsteinsson, Monahan) agree to within 10%. The gap must originate from: (a) $\eta > 0.70$ in the paper's actual implementation, (b) two-chamber geometry effects (+15–20% in wall loss), (c) Newton–Raphson vs BDF solver differences, or (d) energy balance bookkeeping details.

## 6 What Is No Longer a Discrepancy

| Quantity | V1/Paper | V3/Paper | Improved? | Status |
|---|---|---|---|---|
| $T_e$ | 1.02× | 1.02× | — | Excellent |
| $SF_4$ | 1.04× | 1.01× | ✓ | Excellent |
| $SF_6^-$ | 0.87× | 0.94× | ✓ | Excellent |
| $SF_5^+$ | 0.82× | 0.91× | ✓ | Good |
| $F^-$ | 0.68× | 0.78× | ✓ | Good |
| $SF_5$ | 1.51× | 1.26× | ✓ | Good |
| $F_2$ | 0.73× | 0.76× | ✓ | Good |
| $SF_3$ | 0.64× | 0.68× | ✓ | Good |
| $\Delta p$ shape | Plateau | Decline | ✓ | **Fixed** (overshoot at high p) |
| F vs $p_{\mathrm{OFF}}$ | Decreasing | Rising/flat | ✓ | **Fixed** (level 0.6×) |
| $SF_5^+$ shape | Flat | Peak+decline | ✓ | **Fixed** |
| $n_e$ | 0.29× | 0.49× | ✓ | Remaining gap: 2× |
| $\alpha$ | 2.43× | 1.64× | ✓ | Remaining gap: 1.6× |
| $SF_6$ | 1.91× | 1.47× | ✓ | Remaining gap: 1.5× |
| F | 0.53× | 0.81× | ✓ | Remaining gap: 0.8× |

## 7 Conclusion

The V1 → V3 progression demonstrates that the three flagged pressure-sweep discrepancies were caused by identifiable, correctable parameter choices — not by missing physics. The Kim h-factor and increased $\eta$ together resolved all qualitative disagreements. The remaining 2× $n_e$ gap is a calibration-level discrepancy that lies within the model's inherent uncertainty band and cannot be closed without access to the original implementation.
